

## Preliminary Research (Qa-testing)

**Jira** is mainly used for tracking bugs and issues. QA testers can report bugs, assign them to developers, and track their status (open, in progress, resolved). This shows that having a structured way to track issues is very important.

**Slack** is often used for communication between QA and developers. Sometimes bugs or blockers are reported in chat, but messages can get lost and are hard to track later. This suggests that relying only on communication tools is not enough.

QA tools we could use:

- Postman (test backend endpoints like login and updates)
- Cypress (test user flows like submitting updates)
- JMeter (test multiple users submitting updates at the same time)

From a QA tester perspective, the most important aspect of a team status tool is visibility of issues and blockers. For our project, the goal is to build a simple system that allows users to report blockers clearly and track their status. This would help QA testers quickly identify issues, verify fixes, and ensure the system is working correctly.

## User Story

As a QA tester, I want to track reported bugs and blockers clearly, so that I can ensure issues are resolved and the system works correctly.

## User Persona

### Bio:

Daniel is a 30-year-old QA engineer working at a mid-size tech company.

### Lifestyle:

He works closely with developers and product managers. His daily work includes testing features, reporting bugs, and making sure the product is stable before release. He often works under time pressure when deadlines are close.

## Goals

- Ensure the application works correctly before release
- Quickly identify and report bugs
- Track issues until they are resolved

## Frustrations

- Bugs reported in chat tools can get lost
- Hard to track issue status across different tools
- Not always clear if issues are fixed
